I’ve been bitten or scratched. Do I need a rabies vaccine?

Rabies infection can be prevented by a rabies vaccine, even after a bite or scratch from an infected animal occurs (post exposure). The HNHU does not administer the vaccination, but will provide the healthcare provider with the rabies vaccine and rabies immune globulin (RIG) to do so. In most instances, 4 visits, over 2 weeks, are required to receive the injections. These are given into a muscle, not the stomach like was done in the past.

Rabies virus moves very slowly through the human body, ultimately making its way to the brain. It may take months, and even years, before the virus would reach your brain and cause symptoms.

In most cases the animal observation period is sufficient to rule out the need for the victim to receive the post exposure vaccination. However, there are certain situations in which the vaccine may be recommended to you by the Health Unit or your doctor.

- If the bite is to the head or neck, it may be recommended that you begin the vaccinations immediately, and then stop the vaccinations if the animal is confirmed to be healthy after observation.
- If the animal cannot be found to be placed in confinement, or is a wild animal, it may be recommended that you receive the vaccine.
- If the animal is dead it can be tested for rabies, with lab test results usually returned within 48 hours. If it was discovered that the animal had rabies, then the vaccines would be administered.
- If you get bitten on a hand, foot, arm or leg, by a cat, dog or ferret, the animal can be observed for 10 days without the need for vaccination. Vaccine will be provided if it is determined the animal had rabies.
- If the animal gets sick or dies within the 10 days, the Health Unit must be notified immediately. In the event that this occurs, the animal’s brain will be sent for testing and the Health Unit will recommend that the victim contact their doctor to discuss rabies vaccine.

The ultimate decision as to the necessity for rabies vaccine rests with you and your healthcare provider.

Under Ontario law, all cats and dogs over the age of three months in Norfolk and Haldimand Counties must have an up-to-date rabies immunization.

Failure to do so can result in a fine of $180.00

The raccoon strain of rabies has been found in Haldimand County, as shown by an increasing number of raccoons testing positive for the rabies virus since December of 2015. The risk to the public remains low during this outbreak, and no case of human rabies in a local resident has ever been reported.

As recently as 2016, bats, raccoons, stray cats and livestock involved in local biting incidents have tested positive for rabies.

Although rabies is quite uncommon in our area, the disease is almost always deadly once symptoms appear. For this reason, the Haldimand-Norfolk Health Unit must continue to take precautions to protect the health of human animal bite victims and to prevent the spread of the rabies virus.

What happens after I’ve been bitten or scratched?

Rabies is transmitted through the saliva, so when an infected animal bites or scratches a victim the virus can be passed along. However, it is not always possible to determine if an animal has rabies just by observing the way it looks and behaves.

There is a period of time when an animal can have the rabies virus in its saliva but still look healthy.

If you have been bitten or scratched, you should wash the wound immediately for 15 minutes with soap and water, notify your healthcare provider and report the incident to the Health Unit by calling 519-426-6170 or 905-318-6623 between 8:30 - 4:30, or after hours by calling 1-877-298-5888.

When notified of a bite or scratch incident, health inspectors investigate to determine whether or not the animal was contagious with rabies when the bite or scratch occurred.

When the animal is known

- In cases where the animal is known, the inspector will contact the animal’s owner and place the animal under observation and confinement for at least 10 days.
  - The confinement usually takes place at the owner’s home, to limit its contact with people or animals while being observed.
  - This confinement occurs regardless of the rabies vaccination status of the animal, as the vaccine is not 100% reliable.
  - The Health Unit does not order domestic animals euthanized or “put down” for testing if they are healthy and can be confined for observation.
- If the rabies virus was in the animal’s saliva at the time of the bite, it means the virus has already reached the animal’s brain. Within three or four days the animal will begin to develop brain damage, and start to act strange or ill. The brain damage would lead to the death of the animal within the 10 day period.
- If the animal is alive, healthy and has not developed any rabies symptoms in the 10 day period then it did not have rabies in its saliva when the bite occurred, so rabies was not passed along to the person that was bitten or scratched.
- At the end of the 10 day period, the inspector must visually see the animal to verify that it is healthy and alive, and if so the animal can be released.

When the animal is wild, stray or unknown

- If the animal cannot be identified, located and assessed (such as a stray or a wild animal), the Health Unit will always recommend that the victim speak to their healthcare provider about receiving the post exposure vaccination, just to be on the safe side.
- If it is a wild animal that has been captured, it may be euthanized and the specimen sent for rabies testing.
- If you have been bitten or scratched by a bat, or if a bat landed on you, safely capture the bat, if possible. Contact the Health Unit to arrange to have the bat tested for rabies.
- If a bat was discovered in your home and there is a possibility that someone was bitten or scratched without knowing it, contact the Health Unit. The details about your situation will be reviewed by a health inspector, and they will provide you with a recommendation for what actions, if any, to take.
